

GitOps with ArgoCD on AWS EKS

How It Works (Flow)

- 1 Developer commits code or updates K8s YAML
- 2 Code is pushed to GitHub (Repository)
- 3 ArgoCD detects changes and Syncs from Git (Pulls Manifests)
- 4 ArgoCD applies changes to EKS (Desired State)
- 5 EKS pulls Docker images from Amazon ECR
- 6 Ingress + ALB exposes app via domain (xyz.com)
- 7 HPA scales pods automatically
- 8 Monitoring via Prometheus & Grafana (grafana.xyz.com)
- 9 SSL is managed automatically by cert-manager (Let's Encrypt)
- 10 ArgoCD ensures self-healing and keeps cluster in sync
